DOUGLAS AIRCRAFT COMPANY
TORRANCE (C6) FACILITY
PHASE III GROUND WATER AND SOIL
INVESTIGATION WORK PLAN

1.0 INTRODUCTION

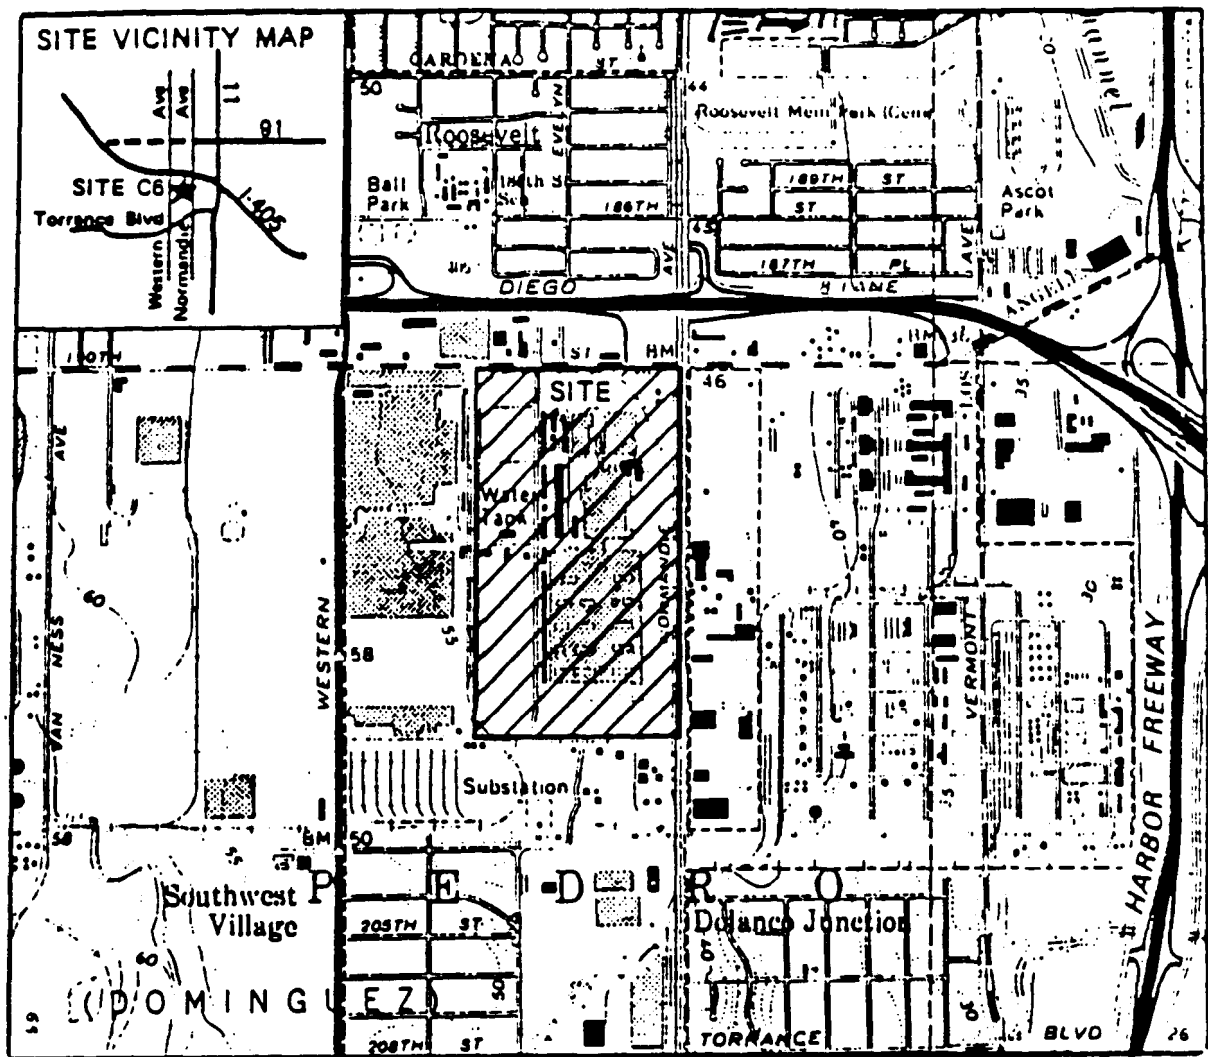

Woodward-Clyde Consultants (WCC) is pleased to present this work plan directed toward the following objectives:

- o To evaluate the vertical and lateral extent of volatile organic compounds (VOCs) in the soil and ground water at the C6 (Torrance) Facility of Douglas Aircraft Company (DAC)
- o To develop data and information on site soil and ground water conditions that would allow design of a remediation program.

The C6 Facility is located at 19503 South Normandie in Los Angeles, California (see Figure 1). The facility is often referred to as the Torrance Facility because of its proximity to the city of Torrance. The suspected source of the VOCs at the facility is Tank Cluster 15T through 18T, located to the south of Building 36 (see Figure 2).

1.1 Previous Investigations

WCC has conducted two previous investigations in this area. The first investigation was directed toward evaluation of the vertical extent of fuel oil in the soil under Building 41 resulting from a pipeline leak associated with Tanks 19T and 20T. The results from this investigation, presented in a report entitled "Leak Investigation at Douglas Aircraft Company's C6 Facility, Los Angeles, California," dated April 1987, indicated the presence of fuel oil to a depth of at least 50 feet below the surface inside Building 41, near the suspected source of the leak.

Fig.
3

Borings advanced outside this building did not encounter fuel oil in the soil, indicating that the lateral extent of fuel oil was apparently confined to the soil column underlying the building. Boring locations for the Phase I investigation are presented on Figure 3.

Ground water samples from a monitoring well (WCC-1) installed downgradient of Tanks 19T and 20T indicated the presence of the halogenated solvents trichloroethylene (TCE), 1,1,1,-trichloroethane (1,1,1-TCA), and 1,1-dichloroethylene (1,1-DCE), as well as benzene. These substances were different from those expected to be present if fuel oil was the source of the compounds in the affected ground water.

The second investigation evaluated the source of organic compounds in the soil and ground water near Tanks 19T and 20T. Results of the investigation are presented in "The Final Report on Phase II of the Subsurface Investigation at Tanks 19T and 20T at the C6 Facility," dated 10 May 1988. This investigation involved installation of four additional observation wells of approximate 90-foot depth and one angle boring, B-4. Boring B-4 was located to the east of Building 41, as shown in Figure 3. The observation well locations are illustrated in Figure 4. ← NC FIG 4

The primary results from the Phase II investigation were as follows:

- o The direction of the ground water gradient is from northwest to southeast (refer to Figure 4). NC
FIG 4
- o Analytical results obtained from water samples collected from Wells WCC-1, -2, -3, -4, and -5 showed the presence of halogenated hydrocarbons, as well as benzene and toluene, in all the water samples. The distribution of organic compound concentrations

appeared to indicate a possible source of these compounds near Tank Cluster 15T through 18T (see Table 1).

- o Data obtained from the observation wells and Boring B-4 indicated that the piping at Tanks 19T and 20T was probably not the source of the organic compounds identified in the ground water; the area near Tank Cluster 15T through 18T, however, appeared to be a possible source. In addition, the petroleum hydrocarbons did not appear to have penetrated more than 50 feet below the surface, and were probably confined to a part of the area under Building 41.
- o Water samples from Well WCC-2, the well upgradient of the suspected source of the release, and from Well WCC-5, the downgradient well, had similar low concentrations of volatile organic compounds, possibly indicating that ground water entering the site contains low levels of these organic compounds.

1.2 Regional Hydrogeologic Setting

The C6 Facility is sited in the Torrance Plain. The following discussion of the regional hydrogeologic setting for the Torrance Plain is based primarily on the United States Geological Survey (U.S.G.S.) Water Supply Paper 1461 (Poland, 1959), the Department of Water Resources (DWR) Bulletin 104, and data from the Los Angeles County Flood Control District (LACFCD).

The major water-bearing aquifers beneath the Torrance Plain in the vicinity of the site, from deep to shallow, include the Silverado (at depths as great as 700 feet), the "400-foot gravel" (also known as the Lynwood Aquifer and referred to herein as such), and the late Pleistocene "200-foot sand" (also known as the Gage Aquifer and referred to herein as such). The Silverado and Lynwood aquifers collectively form the water-bearing zones of the early Pleistocene San Pedro Formation. The upper Pleistocene Lakewood Formation consists of the semi-perched zone, the

Bellflower Aquiclude, and the Gage Aquifer. These are all considered to be shallow aquifers, while the lower Pleistocene aquifers are normally termed deep aquifers.

Areal extent of the aquifers varies over the region. The Silverado and Gage aquifers are continuous from Hawthorne to Palos Verdes. The Lynwood Aquifer, however, thins out considerably in the site vicinity and disappears a few miles to the south.

The site vicinity lacks deposits of recent age that occur over much of the Torrance Plain. Aquifers such as the Gaspur Aquifer (also known as the "50-foot gravel") and alluvium deposits are found in the Santa Monica and Long Beach area, but have not been identified in the vicinity of Torrance.

According to the information obtained from the Los Angeles Flood Control District, the shallow aquifers, including the Gage, are not used for domestic or industrial purposes. Mitchell (1982) of the Water Quality Division of LACFCD has stated that the shallow aquifers are polluted with brines and industrial wastes, rendering them unsuitable for domestic purposes.

The deep aquifers are extensively tapped by wells for various uses and are collectively regarded as the principal water body. Within much of the Torrance Plain, the aquifers of the principal water body are separated by substantial thicknesses of low permeability silt or clay. These beds of silt or clay effectively confine the water in the aquifer and prevent free circulation from one aquifer to another.

For example, nearly 100 feet of silt and clay separate the Gage Aquifer from the Lynwood Aquifer and the Silverado Aquifer from the Lynwood Aquifer in the site vicinity.

Information concerning ground water conditions in the semi-perched aquifers in the area (shallower than the Gage Aquifer) is not available from published literature, nor are these data collected by local water agencies. Data on semi-perched ground water conditions in the area are normally available only from environmental investigations performed by private consulting companies. Pertinent site-specific ground water investigations are discussed in Section 1.3.

Although site-specific data are not available, a generalized statement about the Gage Aquifer at the site may be inferred from drilling logs and water well information obtained for other wells in the region. In the site vicinity, the Gage Aquifer apparently forms a layer of sands and gravels about 50 to 100 feet thick, the top of which occurs approximately 150 feet below ground surface.

Natural recharge of the deep aquifers occurs north of the site in the mountains and alluvial fans bordering the Los Angeles Basin. The shallow and semi-perched aquifers are recharged by direct percolation from the ground surface throughout the basin and by underflow from the recharge areas at the heads of the alluvial fans.

Recharge by precipitation in the Los Angeles Basin occurs primarily during December through April (Dedrick et al., 1977). Mean annual rainfall in the site vicinity is 12 to 14 inches per year (Dedrick et al., 1976, 1977). Natural recharge to all aquifers has been reduced by urbanization

and industrialization in the northern recharge area. Channelizing the Los Angeles and San Gabriel rivers also has reduced recharge to the deep aquifers from these sources. To compensate for the lost natural recharge areas and the heavy use of ground water, artificial recharge programs have been developed.

1.3 Site Hydrogeologic Setting

The present understanding of the site hydrogeology is based primarily on data from environmental investigations conducted by WCC at the C6 Facility (1987) and the Del Amo Hazardous Waste Site (1987), and by Hargis and Associates at the Montrose Facility (1986). These investigations involved evaluations of the soil and ground water conditions beneath the sites; they provide lithologic information on the strata overlying the Gage Aquifer.

The major water-bearing zones of interest beneath the site are the Gage Aquifer and the shallower semi-perched aquifer. Data from the investigation at the Del Amo Hazardous Waste Site, located southeast of the C6 Facility, indicate that the top of the Gage Aquifer is approximately 150 to 160 feet below ground surface. Although not estimated in the investigation, the total thickness of the Gage Aquifer may range from 50 to 100 feet, based on data from adjacent sites.

The semi-perched aquifer is apparently located approximately 70 feet below ground surface at the site and extends to the top of the Gage Aquifer, a depth of approximately 80 feet. Overlying the aquifer are upper Pleistocene deposits of the Lakewood Formation consisting predominantly of silts, clays, and sand zones.

2.0 OBJECTIVE

The objective of this work plan is to present a method of evaluating the lateral and vertical distribution of organic compounds in the soil and ground water near Tank Cluster 15T through 18T. Additionally, WCC will develop the data and information needed to design a soil and ground water remediation program. The specific objectives of this work plan are:

- 1) To evaluate the quality of ground water entering the site.
- 2) To assess the lateral and vertical configuration of the onsite organic compounds in the ground water within the semi-perched aquifer.
- 3) To evaluate the potential for offsite migration of the organics in the ground water.
- 4) To obtain quantitative estimates for aquifer parameters in the shallow and deep zones within the semi-perched aquifer (down to 130 to 150 feet). These parameters will be required for design of a remedial program.
- 5) To estimate the lateral and vertical extent of organics in the soil around Tank Cluster 15T through 18T.

These objectives will be accomplished using the approach described in Section 3.0.

3.0 PROPOSED INVESTIGATIVE PROGRAM

WCC proposes the following program consisting of four tasks.

3.1 Task I - Installation of Observation Wells and Soil Borings Adjacent to Tank Cluster 15T - 18T

Task I involves installation of five shallow (approximately 95 feet) and three deep (approximately 130 to 150 feet) 4-inch diameter observation wells. Plate 1 shows the

proposed locations. These observation wells will be developed, sampled, and analyzed for VOCs by EPA Method 8240 (8240). Well construction and field procedures are discussed in Appendix A.

This task involves partitioning the semi-perched aquifer into an upper and a lower zone. The upper zone wells will be screened from 60 to 95 feet, where static water level is approximately 70 feet below ground surface. The lower zone wells will be screened from approximately 120 to 140 feet. Installation of observation wells within both the upper and lower zones of the semi-perched aquifer is necessary to evaluate differences in vertical hydraulic gradient and concentrations of organic compounds within the semi-perched aquifer.

The Task I well installation program will be implemented as follows:

- o Wells WCC-1D, -3D, -7S, -8S, and -10S will be installed first. Well WCC-10S will be used to evaluate the quality of the ground water entering the C6 Facility from the west. Wells WCC-1D and -3D will provide information on the water quality in the lower portion (130- to 150-foot depth) of the semi-perched aquifer. The location of Wells WCC-7S and -8S will be selected using estimates of the probable lateral spreading of the organic compounds in the ground water based on the observed variation in the direction of the gradient. Wells WCC-7S and -8S will be located, if possible, so that they are at the edges of the zone of ground water with elevated concentrations of organic compounds.
- o Wells WCC-6S, -9S, and -6D will be installed if the results obtained from the earlier well installation indicate that they are needed. Their purpose would be to identify whether organics were present in the ground water at their proposed location. This information could be needed to help delineate the extent of organics in the ground water.

Four or five soil borings approximately 60 feet deep will also be advanced during Task I, to assess the vertical and lateral extent of organic compounds in the soil at Tank Cluster 15T through 18T (see Figure 2 for proposed boring locations). These soil borings will provide information needed to construct geologic cross sections to assist in evaluating the volume of soil with elevated concentrations of organic compounds. Approximately three cross sections will be constructed. This information will be needed for the development of a soil remediation program. Soil samples collected from these borings will be analyzed for VOCs by EPA Method 8240. Soil sampling and field procedures are discussed in Appendix A.

3.1.1 Task IA - Aquifer Slug Testing

Task IA involves conducting slug tests on six shallow and up to three deep observation wells. The slug tests will provide a relatively inexpensive and rapid method of obtaining preliminary estimates of horizontal hydraulic conductivity in the shallow and deep zones within the upper aquifer. These data will assist in evaluating the horizontal and vertical ground water velocity and the potential areal configuration of the organics in the ground water.

3.2 Task II - Installation of Additional Observation Wells

Task II may include installation of an additional three or four shallow and two or three deep observation wells for further delineation of organics in the ground water, if necessary. These wells will also provide additional information for remediation design parameters, such as number of recovery wells, volume of ground water, and treatment time. The exact number and locations of

additional observation wells, if any, will depend on analytical data, aquifer characteristics, and lithologic data collected during Tasks I and IA.

If organic compounds appear to be present in the deep observation wells installed in Tasks I and II, installation of an observation well(s) in the Gage Aquifer (depth of 180 to 200 feet) may be necessary to evaluate whether organic compounds have migrated through the clay layers overlying the Gage Aquifer.

All observation wells installed under Task II will be constructed, developed, and sampled as described in Appendix A.

3.2.1 Task IIA - Aquifer Slug Testing of Task II Observation Wells

Task IIA involves aquifer slug tests for the additional observation wells installed during Task II. A maximum of six slug tests between the shallow and deep wells will be conducted. These tests will provide additional information for estimating deep and shallow aquifer characteristics and refinement of the vertical and lateral extent of organic compounds in the ground water.

3.3 Task III - Recovery Well and Aquifer Testing

Task III will involve installing one 6-inch pumping/recovery well (RW-1) and conducting one 48-hour aquifer pumping test on RW-1. This test will be conducted to evaluate aquifer characteristics under pumping "stress" in the shallow and deep zones of the semi-perched aquifer. Aquifer pumping tests can provide more representative aquifer data than slug tests, because they generate a larger radius of influence

than slug tests. Data from this test, combined with data from slug tests (Tasks IA and IIA), will provide aquifer parameter information such as transmissivity, storativity, radius of influence, and specific capacity, which will be required for development of a ground water remediation program. The data will also allow better assessment of ground water velocity and potential migration distance of organic compounds.

The approximate location of RW-1 is illustrated on Plate 2. The total depth and screened interval of this well will depend on ground water analytical results from Wells WCC-3S and -3D. If organic compounds are found in the shallow zone (Well WCC-3S), but not in the deep zone (Well WCC-3D), RW-1 will be screened only in the upper zone to minimize the potential for organic compounds migrating into the lower section of the aquifer. However, if analytical results from Wells WCC-3S and -3D indicate organic compounds in the shallow and deep aquifer zones, RW-1 will be screened through the upper and lower zones.

Task III will also include selection and installation of a pilot ground water treatment system designed to treat the ground water produced by the aquifer pump test, which could total an estimated 150,000 gallons. Depending on the results from task activities described above, the treatment system may consist of either a portable, trailer-mounted, mobile facility or actual installation of a pilot treatment facility for ground water produced from the aquifer pump tests.

3.4 Task IV - Final Report Preparation

Task IV will involve the compilation, analysis, and evaluation of the data generated under this work program.

The results of this evaluation will be integrated with data from previous investigations and used to prepare a summary report. This report will include the following elements:

- o A discussion of the geologic and hydrogeologic framework controlling migration of organics at the site
- o A description of drilling, sampling, and analytical procedures utilized in the completion of task activities
- o A discussion of the results obtained from the soil and ground water sampling program
- o Estimates of the lateral and vertical extent of organic compounds in the ground water and soil around Tank Cluster 15T through 18T.

4.0 SCHEDULE

WCC proposes completing this investigation within approximately eight months from receiving authorization from DAC to proceed and following approval of the work plan by the Los Angeles Regional Water Quality Control Board. The proposed schedule is presented in Plate 2, and a critical path flow chart is provided in Plate 3.

APPENDIX A
FIELD PROCEDURES AND METHODOLOGY

(d-bj/dacappa)

APPENDIX A
FIELD PROCEDURES AND METHODOLOGY

A.1 GENERAL INFORMATION

A.1.1 Observation Well Installation - Shallow

Shallow observation wells will be constructed of 4-inch O.D., Schedule 40, PVC casing and screen and set to a depth of about 95 feet. The shallow observation wells will be installed by drilling a 95-foot deep hole with a nominal 10-inch O.D. hollow-stem auger. A wooden plug will be placed in the lead cutting auger to prevent cuttings and water from entering the inside of the auger. Municipal water may be added to the inside of the auger as drilling progresses through the water table to offset hydrostatic pressure of any fine-grained flowing sands outside the auger. During the Phase II investigation (18 April 1988), two attempts were made to install Well WCC-3 without the use of water; however, the bottom 3 to 5 feet of the auger "sanded-in" immediately after knocking out the wooden plug. The "sanding-in" of the auger prevented the wells from being properly constructed. Subsequently, water had to be used for proper construction of Wells WCC-2, -3, -4, and -5. The volumes of municipal water used in the construction of each well will be noted on the well log forms, and samples of municipal water will be collected for possible laboratory analysis.

A.1.2 Well Construction - Shallow

The shallow observation wells will be constructed of 4-inch O.D., Schedule 40, PVC flush-threaded blank pipe. We anticipate that the wells will be screened with 0.010-inch slot screen, but actual slot size will be dependent on soil
